Clinical History: A 1.5-year-old, intact female Syrian hamster (*Mesocricetus auratus*) presented for bilaterally closed eyes, anorexia, adipsia, and lethargy with watery stool or vaginal discharge for the previous two days. The animal had been presented four months prior with similar clinical signs. At that time, there were no significant changes on bloodwork and radiographs were unremarkable; however, mild bicavitary effusion, a single cystic lesion of the liver and a single cystic abdominal lymph node were found on ultrasound. This time, physical exam revealed dehydration, weight loss (35% body weight), yellow vaginal discharge, a mass at the cranial thorax, and respiratory distress. A complete blood count revealed leukopenia with neutropenia. Due to poor prognosis, the hamster was humanely euthanized.

**Necropsy Findings**: The hamster was in thin body condition (3.5/9). A subcutaneous, round, loosely attached mass measuring approximately 1 cm in diameter was present in the ventral neck. The mass had raised, pale tan, nodular areas that were well demarcated from smooth, pale pink areas. On cut surface, the mass was diffusely pink.
